

Compute Pipelines with Advanced Data Management using Pegasus WMS

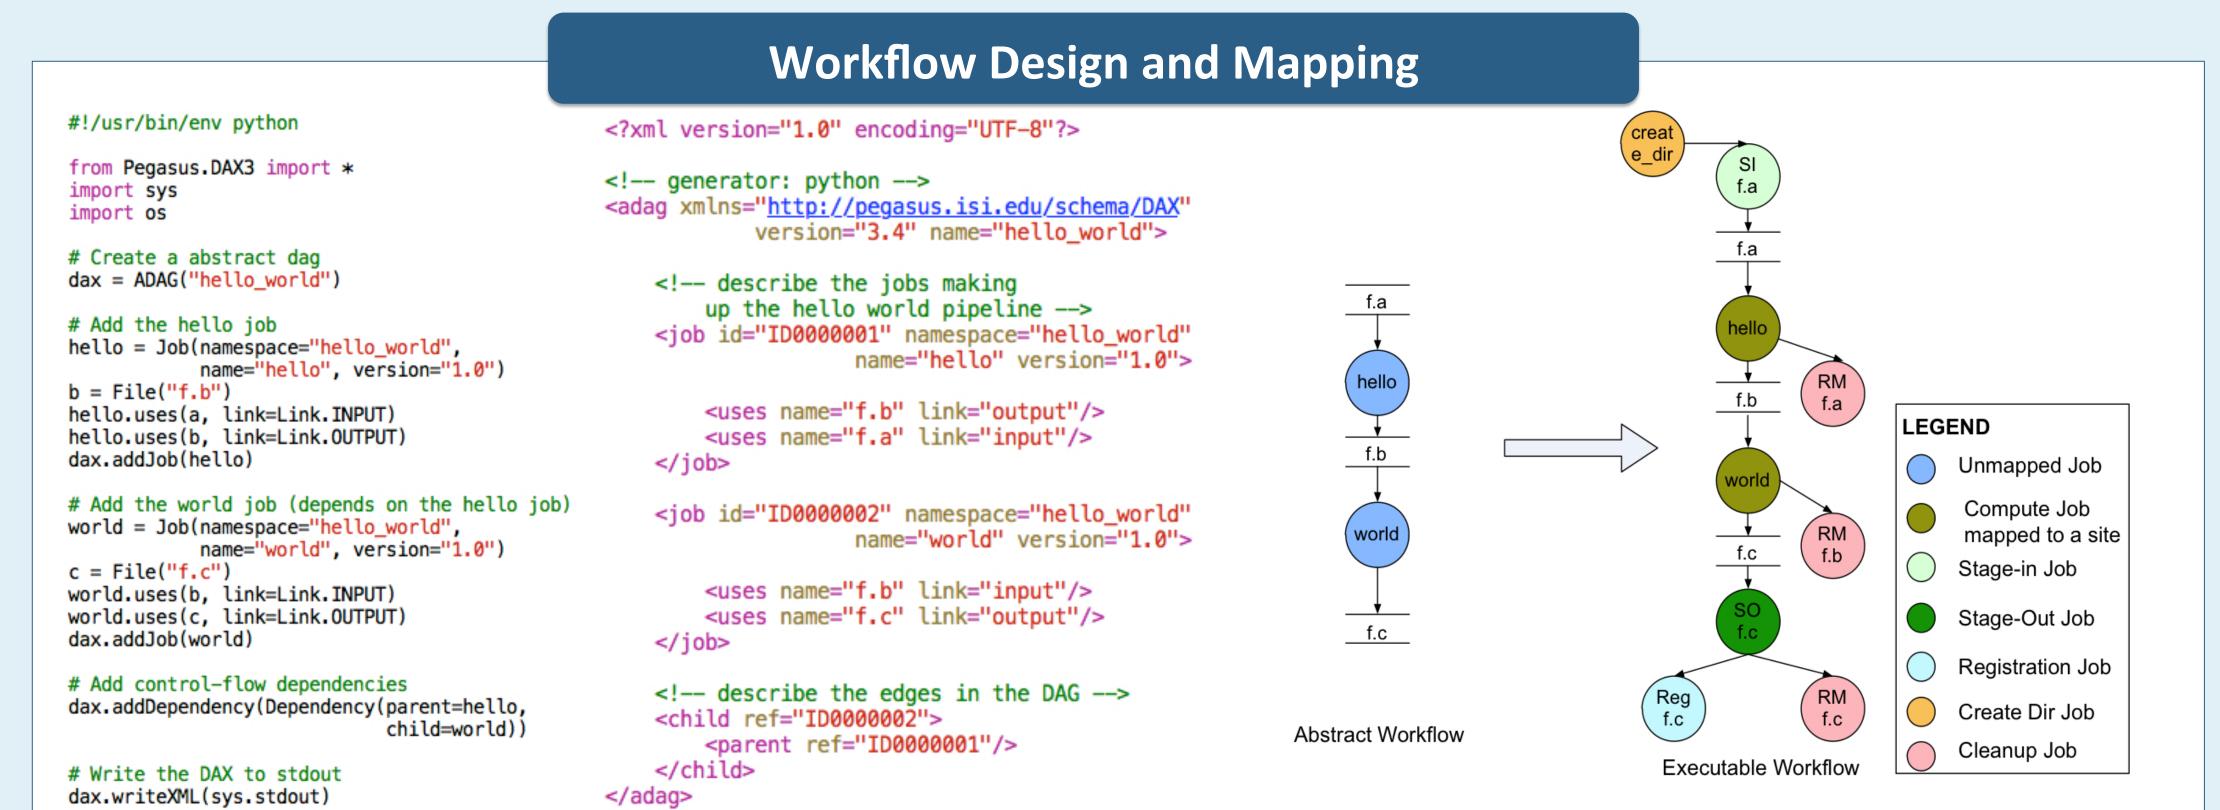

Karan Vahi, Mats Rynge, Rafael Ferreira da Silva, Gideon Juve, Rajiv Mayani, Ewa Deelman University of Southern California / Information Sciences Institute

Overview

- Pegasus is a system for mapping and executing abstract application workflows over a range of execution environments.
- The same abstract workflow can, at different times, be mapped different execution environments such as XSEDE, OSG, commercial and academic clouds, campus grids, and clusters.
- Pegasus can easily scale both the size of the workflow, and the resources that the workflow is distributed over. Pegasus runs workflows ranging from just a few computational tasks up to 1 million.
- Pegasus Workflow Management System (WMS) consists of three main components: the Pegasus Mapper, HTCondor DAGMan, and the HTCondor Schedd.

DAX Generator API

Easy to use APIs in Python, Java and Perl to generate an abstract workflow describing the users computation.

Above is a simple two node hello world example.

Abstract Workflow (DAX)

The abstract workflow rendered as XML. It only captures the computations the user wants to do and is devoid of any physical paths. Input and output files are identified by logical identifiers. This representation is portable between different execution environments.

Abstract to Executable Workflow (Condor DAG) Mapping

The DAX is passed to the Pegasus Mapper and it generates a HTCondor DAGMan workflow that can be run on actual resource.

The above example highlights addition of data movement nodes to staging in the input data and stage out the output data; addition of *data cleanup nodes* to remove data that is no longer required; and *registration nodes* to catalog output data locations for future discovery.

Data Reuse Example LEGEND Unmapped Job Compute Job mapped to a site A Compute Job mapped to a site B Stage-in Job Stage-Out Job Registration Job Create Directory Job Cleanup Job **Abstract Workflow** Final Executable Workflow Clustered Job

Additional Capabilities Highlighted

runtime statistics and exit status.

Data Reuse: Jobs B and D are removed from the workflow as file f.d already exists. The f.d is staged in , instead of regenerating it by executing jobs B and D.

Job Clustering: Jobs C and E are clustered together into a single clustered job.

Cross Site Run: Single Workflow can be executed on multiple sites, with Pegasus taking care of the data movement between the sites.

Monitoring and Debugging

At runtime, a database is populated with workflow and

task runtime provenance, including which software was

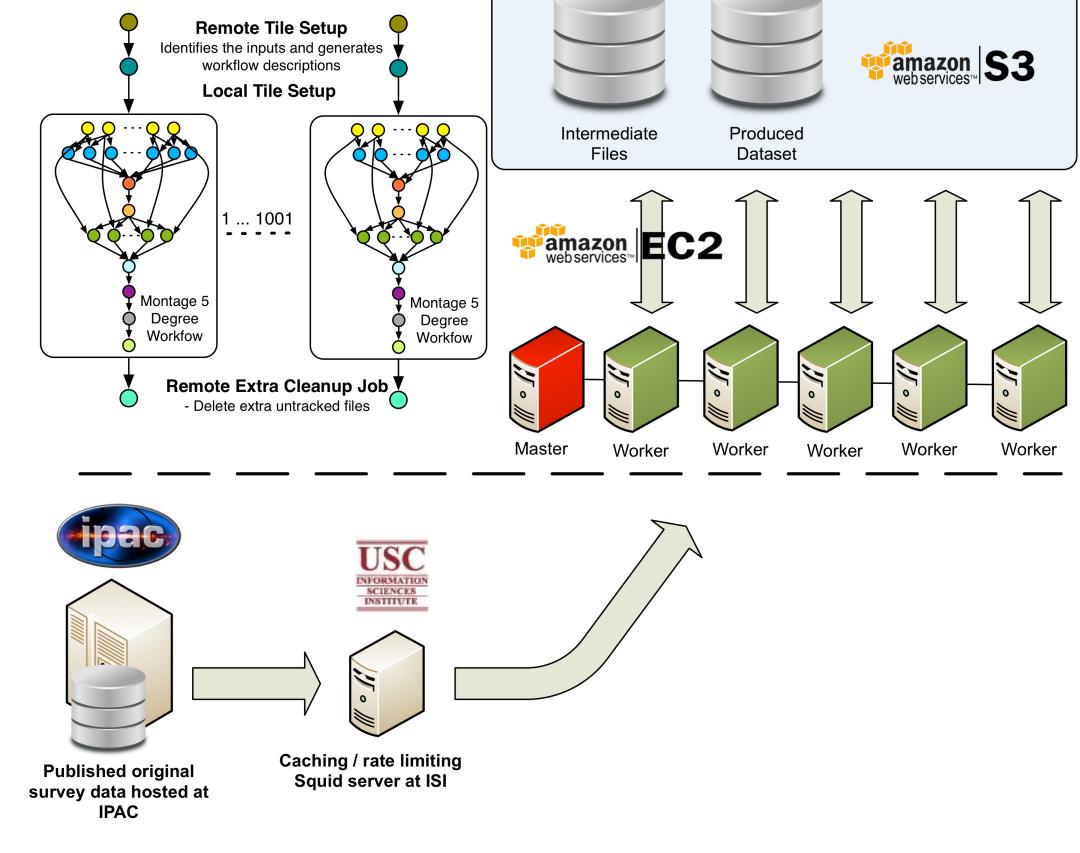

Pegasus comes with command line monitoring and

debugging tools. A web dashboard now allows users to

monitor their running workflows and check jobs status

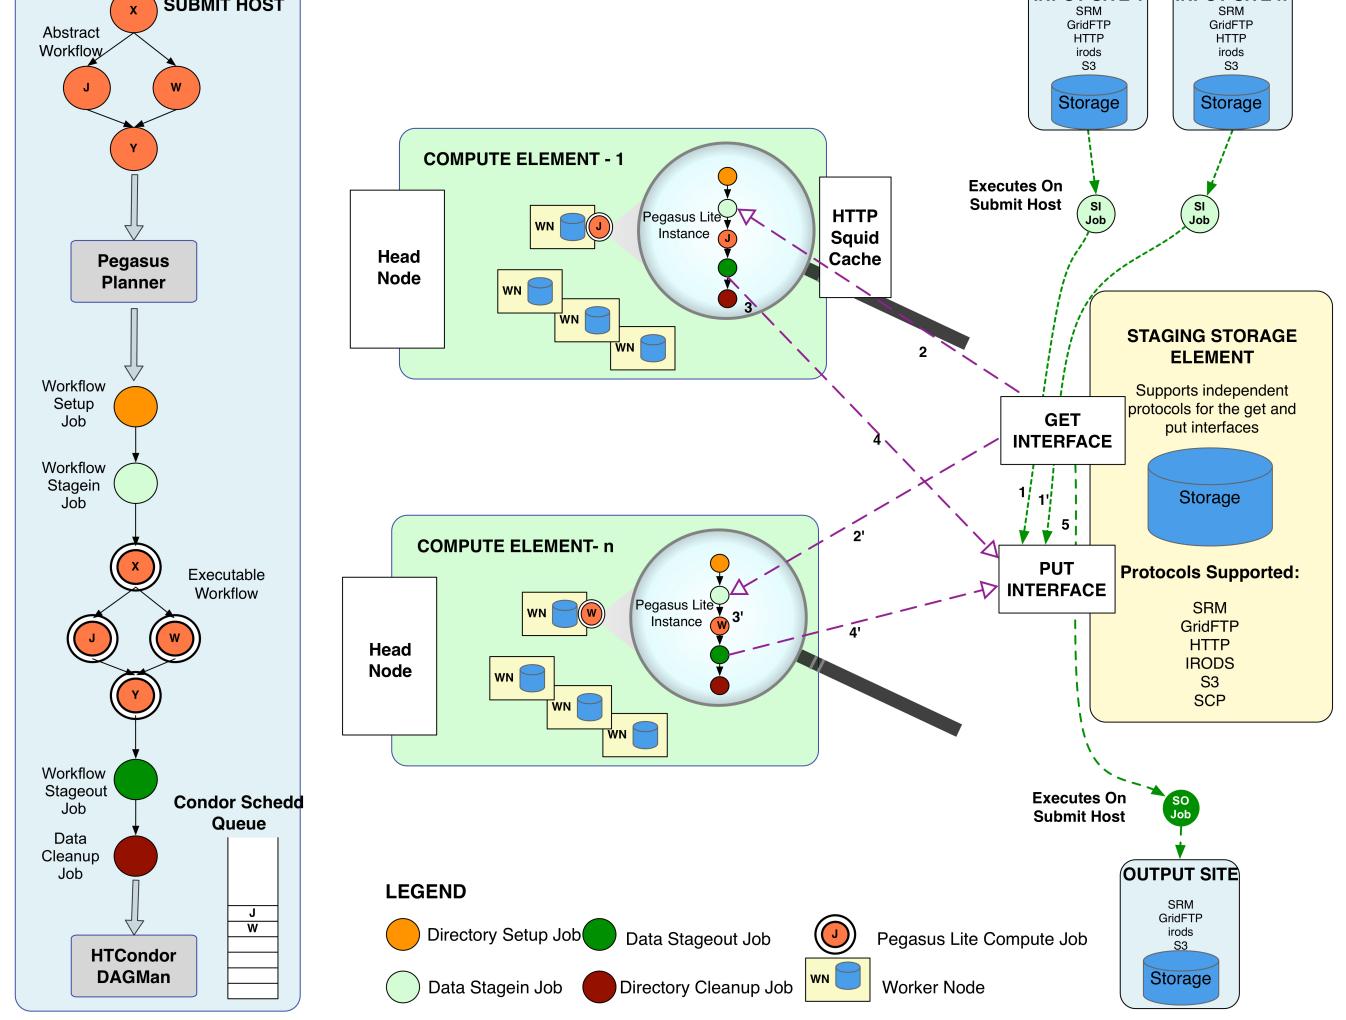

used and with what parameters, execution environment,

Example: Montage Galactic Plane

- Generates mosaics from existing IPAC datasets
- Used to generate tiles 360 x 40 around the galactic equator
- Tiles are 5° x 5° with 1° overlap with neighbors
- One workflow for each of 17 bands (wavelengths)
- Each workflow uses 3.5TB of input imagery (1.6 million files)
- Each workflow consumes 30K CPU hours and produces 1,001 tiles in FITS format – data to be published publically in Amazon S3

Data Flow For Pegasus Workflows at Runtime

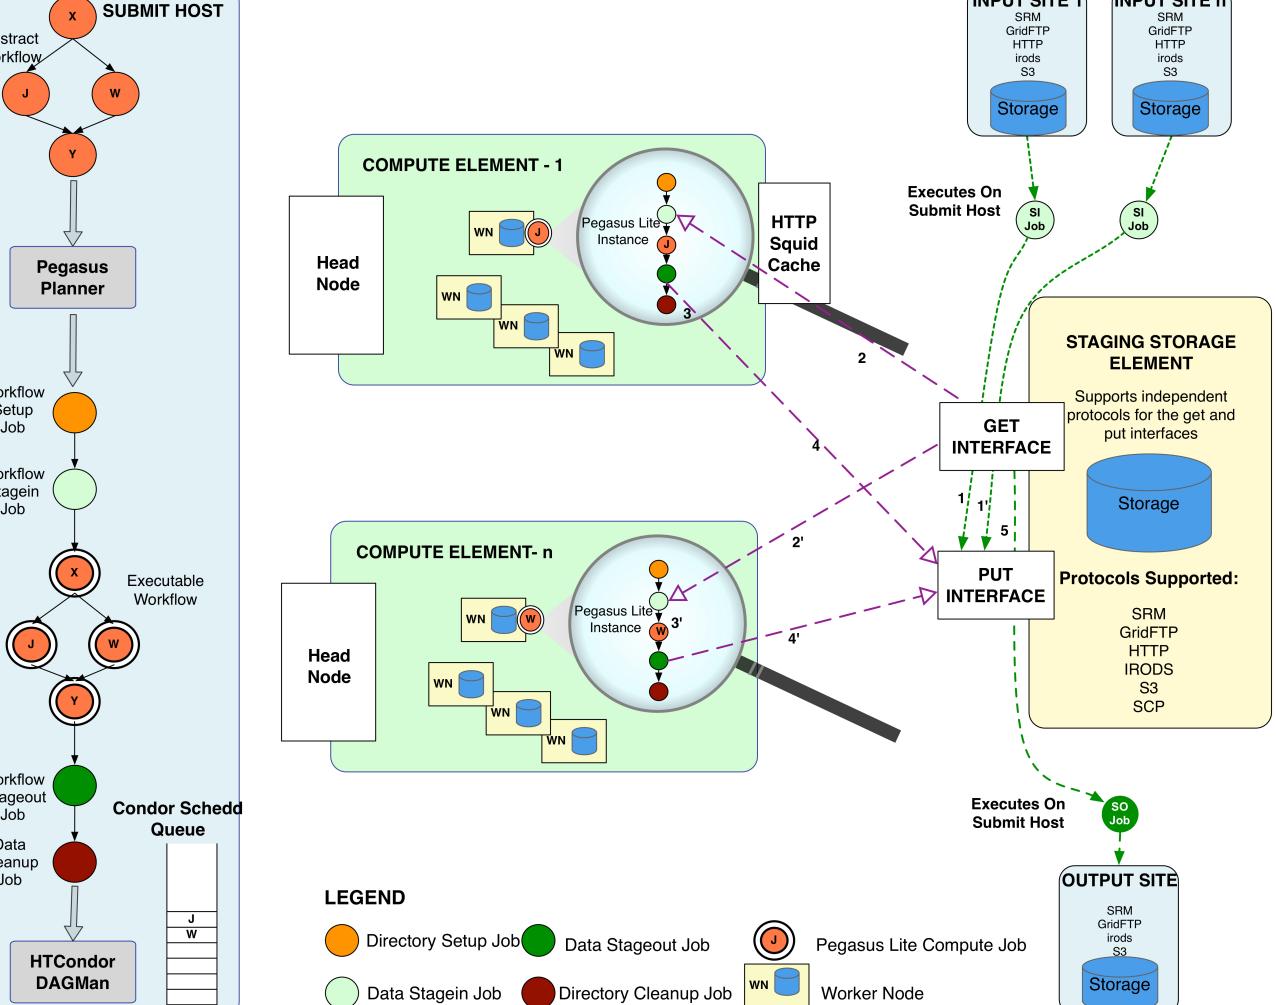

Pegasus Data Staging Configurations

Non Shared Filesystem with Staging Site: Data is staged by Pegasus Lite at runtime from an external staging site. Popular on OSG with SRM as data staging server.

CondorIO Data is staged using Condor File Transfers from submit node. Popular on OSG and Cloud Environments.

Shared Filesystem (Head Node and the worker nodes of execution sites share a filesystem). Popular on XSEDE and clusters.

1. Stagein Jobs transfer input data for the workflow to the staging

site 2. Pegasus Lite wrapped jobs, when they start on compute worker

nodes, pull in the input data from

Data Flow For a Workflow with

Pegasus

3. The compute job executes on a local directory on the worker node.

staging site

- 4. The PegasusLite wrapper pushes the output data from the worker node back to the staging site
- 5. The Stageout Jobs transfer the relevant output data out to the output site from staging site

and output.

Acknowledgments:

- Pegasus WMS is funded by the National Science Foundation OCI SDCI program grant #1148515.
